Digital terrain analysis provided support for the existence of global lineaments: on catchment area maps of Earth, it was possible to detect five mutually symmetrical pairs of helical structures encircling the planet from pole to pole. On catchment area maps of Mars and Venus, it also was possible to detect several helical structures.

A digital elevation model (DEM) is a powerful surface model of the Earth or of any other planets. It can provide explicate and more inherently hidden

information of the topographic complexity, in a simplified way.

An important problem in terrain analysis is modeling how water flows across a terrain and creates floods by filling up depressions. In this paper, we study a number of flood-risk related problems: given a terrain Σ , represented as a triangulated xy-monotone surface with n vertices, a rain distribution R , and a volume of rain Ψ , determine which portions of Σ are flooded.
