In meteorology, the planetary boundary layer, also known as the atmospheric boundary layer or peplosphere, is the lowest part of the atmosphere and its behaviour is directly influenced by its contact with a planetary surface. On Earth it usually responds to changes in surface radiative forcing in an hour or less. In this layer physical quantities such as flow velocity, temperature, and moisture display rapid fluctuations and vertical mixing is strong. Above the PBL is the "free atmosphere", wher

Boundary-layer schemes are essential components of numerical weather-forecasting and climate models. From simple beginnings 50 years ago, they have grown in sophistication and detail. Here, we review development and discuss the key processes to be represented and how they have most commonly been parametrized.

The planetary boundary layer (PBL) is the bottom layer of the troposphere in contact with the surface of the earth. As a critical component of the earth's climate system, the PBL controls exchanges of heat, momentum, moisture, and chemical constituents between the surface and free atmosphere.
